

High Performance NTP Server using FPGA

Hiroshi Toriyama, Akihiko Machizawa, Tsukasa Iwama

*National Institute of Information and Communications Technology
NICT, Japan*

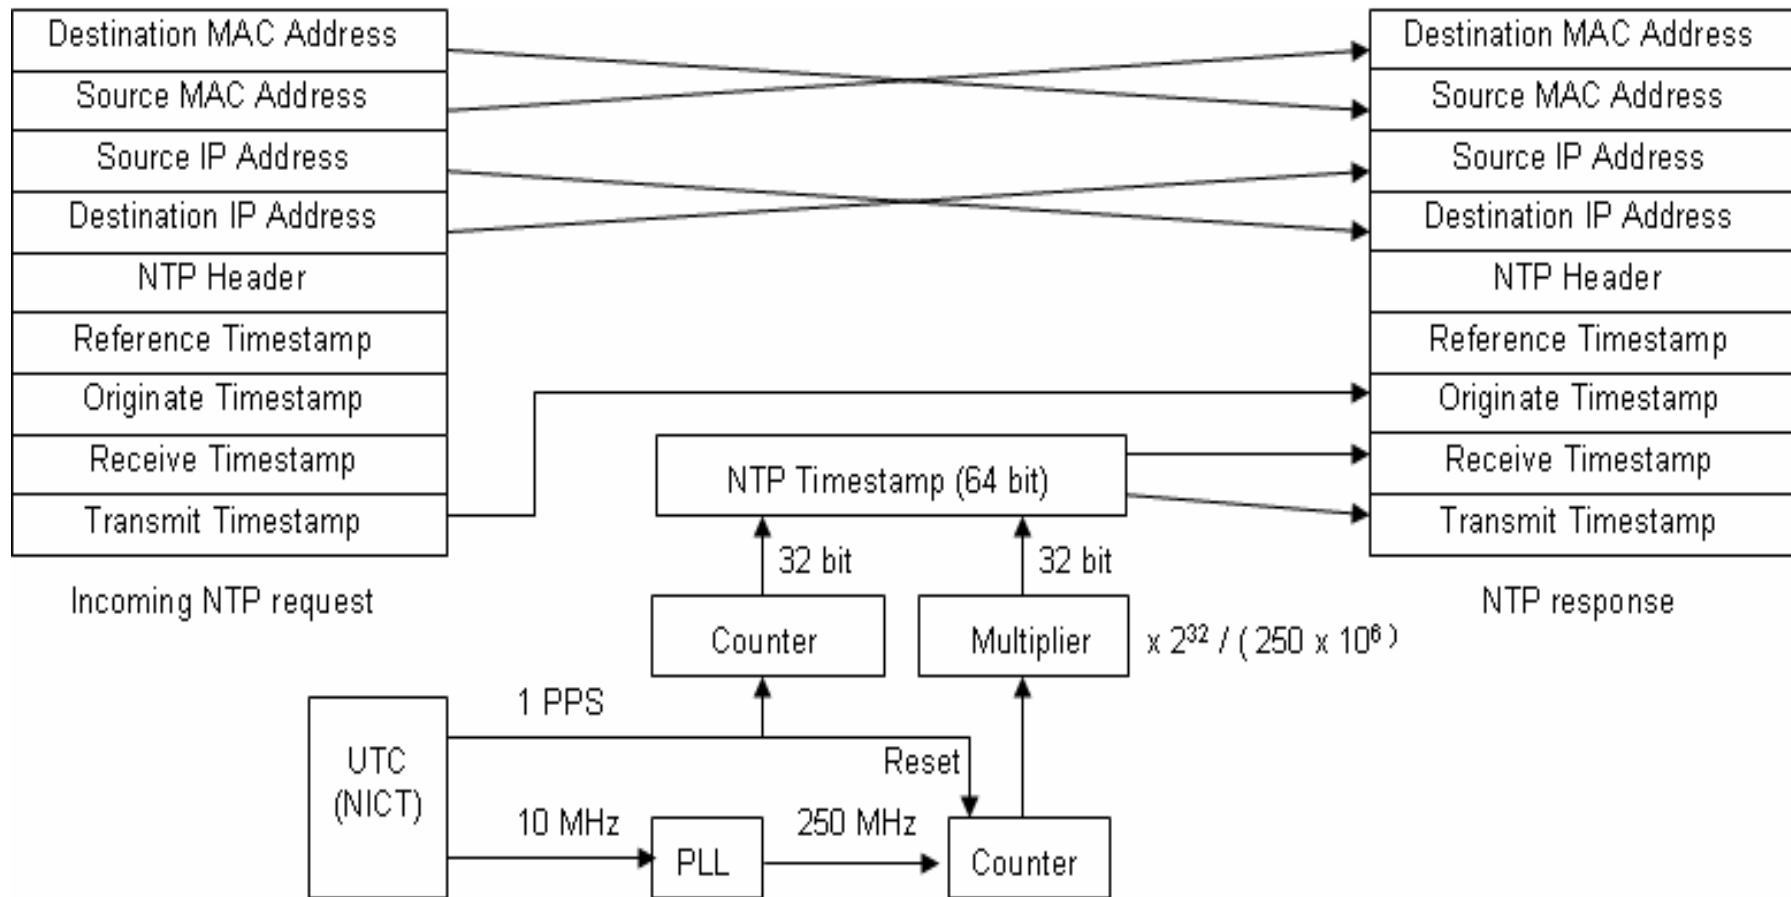

Simple Functions (subset of SNTP)

- NTP server request / response
- Single Reference Clock
- IPv4 and IPv6 unicast

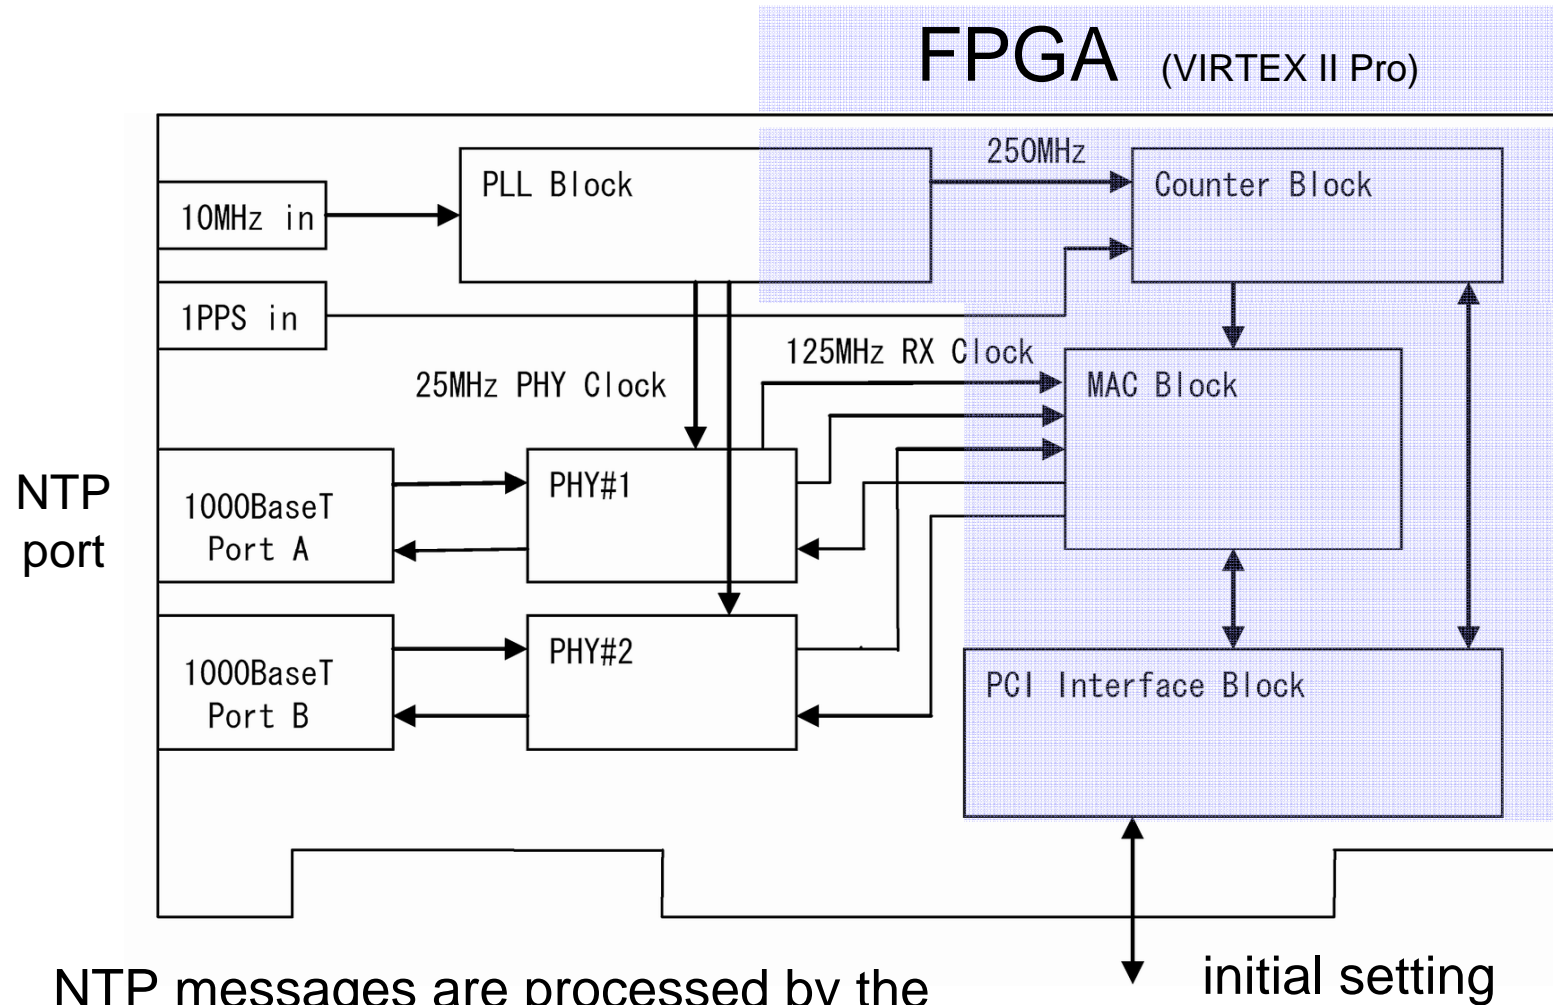

High Performance

- 8 ns accuracy
- 1 Gbps wire-speed throughput
- Intrusion tolerant

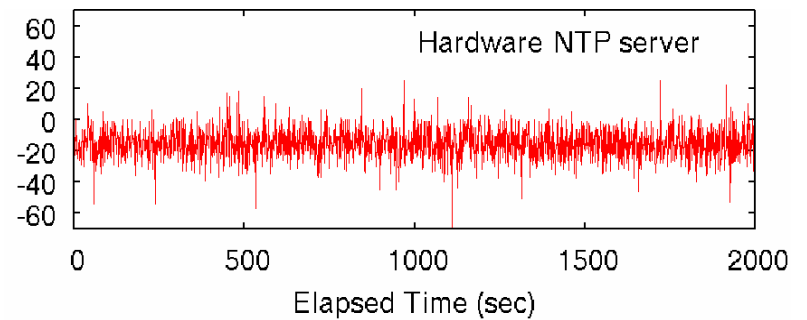

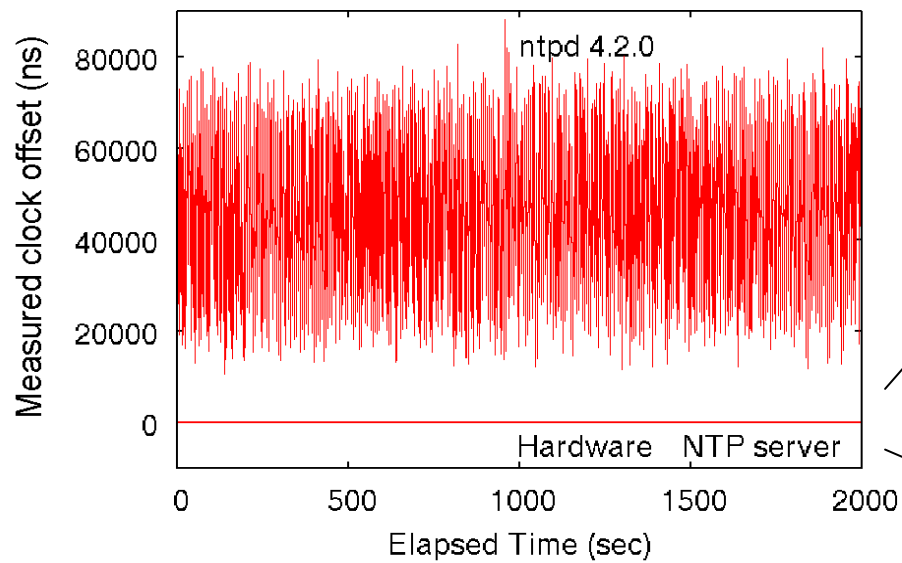

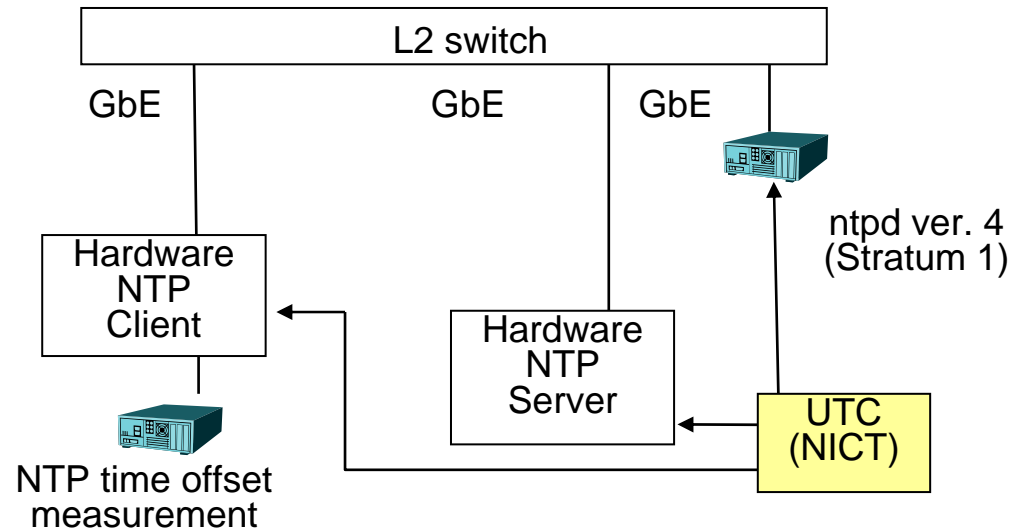

Processing Ethernet frame directly

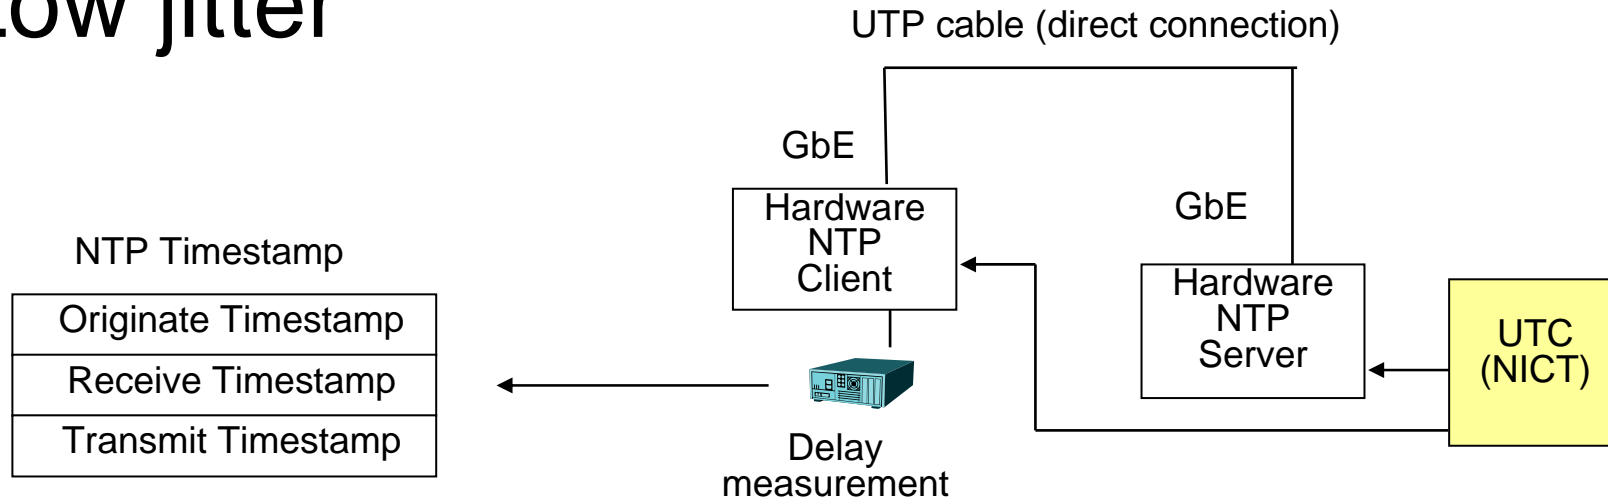

Hardware implementation

Low jitter

Low jitter

$$\text{Delay} = (\text{Receive Timestamp}) - (\text{Originate Timestamp})$$

Purposes of our server

- Stratum 1 public NTP server
 - Up to 1 million requests per second
 - Intrusion tolerant
- Accurate Time-transfer
 - ~ 50ns within Local Area Network
 - ~ 1 μ s using High-speed backbone

Future plan

- Access rate limitation:
using the hash table of source IP addresses.
- Reliability improvement:
checking the clock signal using internal OCXO.
- Security improvement:
developing server authentication method with
keeping some performance.
